#### Abstract

A number of trivalent graphs, in particular variants of the cube-connected cycles and shuffle-exchange, have become popular as interconnection patterns for synchronous parallel computers. We consider highly-structured interconnection patterns that allow large parallel machines to be constructed from isomorphic copies of smaller ones, plus (perhaps) a few extra processors. If only a small number of extra processors are added, we call the interconnection pattern recurrent. If no extra processors are added, we call it recursive. We show that a constant-degree recursive interconnection pattern is, in a sense, not as versatile as the cube-connected cycles or shuffle-exchange, and we present a trivalent recurrent interconnection pattern that is.

Keywords: Parallel computation, interconnection pattern, composite algorithm, cube-connected cycles

## 1. Introduction

An interconnection pattern is an infinite series $G=\left(G_{0}, G_{1}, G_{2}, \ldots\right)$ of finite graphs. Graph $G_{n}$ represents a parallel machine, each vertex a processor, and each edge a communication link between processors. The processor bound $\mathrm{P}(\mathrm{n})$ is the number of vertices in $G_{n}$ as a function of $n$. For an interconnection pattern to be of any practical use, the following properties must hold:
(1) The degree of $G_{n}$ is constant (i.e., independent of $n$ ).
(2) $G_{n}$ is easy to compute (as a function of $n$ ).
(3) There is a constant $\mathrm{c}>0$ such that, for all $\mathrm{n} \geqslant 1, \mathrm{P}(\mathrm{n}) \leqslant \mathrm{c} P(\mathrm{n}-1)$.

The literature already provides us with useful interconnection patterns. Preparata and Vuillemin [5] studied a useful class of algorithms (which they call composite algorithms) for the multi-dimensional cube. Although this interconnection pattern has nonconstant degree, they presented a practical interconnection pattern, called the cube-connected cycles, which has the ability to simulate composite
algorithms without asymptotic time loss. We call a practical interconnection pattern with this property composite. The shuffle-exchange interconnection pattern [7] is also easily seen to be composite. There are efficient composite algorithms for many useful data routing problems (such as sorting and performing permutations), which can thus efficiently be implemented on either the cube-connected cycles or shuffle-exchange.

Loosely speaking, an interconnection pattern is said to be recurrent if each graph $\mathrm{G}_{\mathrm{n}}$ is made up of many isomorphic copies of smaller graphs $G_{m}$ where $\mathrm{m}<\mathrm{n}$. Both the cube-connected cycles and shuffle-exchange are composite, but neither is recurrent. Meyer auf der Heide [2,3] has given a degree-4 interconnection pattern that is both composite and recurrent. We present a degree-3 interconnection pattern with the same properties. Each $\mathrm{G}_{\mathrm{n}}$ is made up of at least $\mathrm{P}(\mathrm{n}) /(2 \mathrm{P}(\mathrm{m}))$ copies of $\mathrm{G}_{\mathrm{m}}$. Also, we find that it is impossible to design a composite interconnection pattern with the property that each $\mathrm{G}_{\mathrm{n}}$ is made up of exactly $\mathrm{P}(\mathrm{n}) / \mathrm{P}(\mathrm{m})$ copies of $\mathrm{G}_{\mathrm{m}}$. We call an interconnection pattern
with the latter property recursive.
The main body of this paper is divided into two sections. In Section 2 we demonstrate that no recursive interconnection pattern can permute $n$ items in $\mathrm{O}(\log \mathrm{n})$ time, a task that is well within the abilities of a composite interconnection pattern. In Section 3 we give a composite recurrent interconnection pattern, which we call the cubeconnected lines. A preliminary version of the results of this paper has appeared in [4].

## 2. Recursive interconnection patterns

An interconnection pattern $G=\left(\mathrm{G}_{0}, \mathrm{G}_{1}, \ldots\right)$ with $\mathrm{P}(\mathrm{n})$ processors is said to be recurrent if, for all $\mathrm{n}, \mathrm{m}$ with $0 \leqslant \mathrm{~m} \leqslant \mathrm{n}, \mathrm{G}_{\mathrm{n}}$ has $\Omega(\mathrm{P}(\mathrm{n}) /(\mathrm{P}(\mathrm{m}))$ disjoint subgraphs isomorphic to $G_{m}$. The simplest form of recurrence one might choose is to have $\mathrm{G}_{\mathrm{n}}$ constructed from precisely $\mathrm{P}(\mathrm{n}) / \mathrm{P}(\mathrm{m})$ such subgraphs. Unfortunately, this type of recurrent interconnection pattern is much less powerful than the shuffle-exchange [7] or cube-connected cycles [5] interconnection patterns.

Suppose c is a fixed positive integer (independent of n ). More precisely, a recursive interconnection pattern is one in which $G_{n}(n>0)$ is made up of exactly c disjoint copies of $G_{n-1}$ (with some fixed graph for $G_{0}$ ), joined by extra edges from some graph $\mathrm{G}_{\mathrm{n}}^{\prime}$.

Theorem 2.1. A constant degree recursive parallel machine with $\mathrm{P}(\mathrm{n})$ processors cannot permute $\mathrm{P}(\mathrm{n})$ items in $\mathrm{O}(\log \mathrm{P}(\mathrm{n}))$ steps.

Proof. For a contradiction, suppose $\mathrm{G}=$ ( $\mathrm{G}_{0}, \mathrm{G}_{1}, \ldots$ ) is a $\mathrm{P}(\mathrm{n})$-processor, degree-d recursive interconnection pattern that can be used to permute $\mathrm{P}(\mathrm{n})$ items in $\mathrm{O}(\log \mathrm{P}(\mathrm{n}))$ time. The following simple and elegant technique is due to Meertens [1].

Without loss of generality assume $\mathrm{P}(0)=1$ (note that this means $\mathrm{P}(\mathrm{n})=\mathrm{c}^{\mathrm{n}}$ ). For convenience, write $P_{n}$ for $P(n)$. Let $E_{n}$ denote the number of edges in $\mathrm{G}_{\mathrm{n}}, \mathrm{E}_{\mathrm{n}}^{\prime}$ denote the number of edges in $\mathrm{G}_{\mathrm{n}}^{\prime}$, and $\Gamma_{n}=E_{n} / P_{n}$. Note that $\Gamma_{n} \leqslant \frac{1}{2} d$. (Let $\mathrm{S}_{\mathrm{n}}$ be the sum over all vertices $v$ in $G_{n}$ of the number of edges incident with $v$. Clearly, $\mathrm{S}_{\mathrm{n}} \leqslant \mathrm{d} \mathrm{P}_{\mathrm{n}}$. But every edge
is counted twice, so $S_{n}=2 E_{n}$.)
We claim that, for $n \geqslant 1, E_{n}^{\prime}=\Omega\left(c^{n} / n\right)$. Consider one of the subgraphs of $G_{n}$ isomorphic to $\mathrm{G}_{\mathrm{n}-1}$. Pick a permutation that takes a data item from each vertex of the subgraph (there are $\mathrm{c}^{\mathrm{n}-1}$ of them) to a vertex of $G_{n}$ outside that subgraph. These data items must pass along the edges of $\mathrm{G}_{\mathrm{n}}^{\prime}$, since these are the only edges linking the subgraph with the rest of $G_{n}$. Thus, in one step at most $E_{n}^{\prime}$ items can be moved. By hypothesis we can move all the items in $\mathrm{O}(\mathrm{n})$ steps. There are $\mathrm{c}^{\mathrm{n}-1}$ items to be moved. Hence, $c^{n}=O\left(E_{n}^{\prime} n\right)$. This is sufficient to prove the above claim.

Therefore,

$$
\begin{array}{rlr}
E_{n} & =E_{n}^{\prime}+c E_{n-1} \\
& =\sum_{i=1}^{n-1} c^{i} E_{n-i}^{\prime} \\
& =\Omega\left(\sum_{i=1}^{n-1} c^{i} c^{n-i} /(n-i)\right) & \text { (by the claim) } \\
& =\Omega\left(\sum_{i=1}^{n-1} c^{n} / i\right) \quad \text { (by re-indexing). }
\end{array}
$$

Thus,
$\Gamma_{n}=E_{n} / P_{n}=\Omega\left(\sum_{i=1}^{n-1} 1 / i\right)$,
which diverges as $\mathrm{n} \rightarrow \infty$. But this contradicts the fact that $\Gamma_{n} \leqslant \frac{1}{2} d$, a constant independent of $n$. Thus, no such parallel machine can exist.

This is in contrast to the corresponding result for the cube-connected cycles (see [5]) and shuffle-exchange (see [4]).

## 3. A recurrent interconnection pattern

First, let us introduce some useful notation. Suppose $v$ and $i$ are nonnegative integers. If $i \geqslant 1$, then let $v_{i}$ denote the ith least-significant bit in the binary representation of $v$, that is, $v_{i}$ $=\left\lfloor\mathrm{v} / 2^{(\mathrm{i}-1)}\right\rfloor \bmod 2$. Where convenient, we may confuse the integer v and a binary representation $\mathrm{v}_{\mathrm{k}} \mathrm{v}_{\mathrm{k}-1} \ldots \mathrm{v}_{\mathbf{1}}$ (where $\mathrm{k} \geqslant\lfloor\log \mathrm{v}\rfloor+1$ ) of v . Also, let $v^{(1)}$ denote the integer that differs from $v$ precisely
in the i th (least-significant) bit, that is, $\mathrm{v}^{(\mathrm{i})}=\mathrm{v}+$ $(-1)^{v_{i}} 2(i-1)$.

The cube-connected cycles $\mathrm{CCC}_{\mathrm{k}}$ of Preparata and Vuillemin [5] is defined as follows. Let $r$ be such that $2^{\mathrm{r}-1}+\mathrm{r}-1<\mathrm{k} \leqslant 2^{\mathrm{r}}+\mathrm{r} . \quad \mathrm{CCC}_{\mathrm{k}}$ has vertex-set
$\left\{(\mathrm{v}, \mathrm{p}) \mid 0 \leqslant \mathrm{v}<2^{\mathrm{k}-\mathrm{r}}, 0 \leqslant \mathrm{p}<2^{\mathrm{r}}\right\}$,
and each vertex ( $\mathrm{v}, \mathrm{p}$ ) is joined to the following vertices
(i) $\left(\mathrm{v}^{(\mathrm{p}+1)}, \mathrm{p}\right)$, provided $0 \leqslant \mathrm{p}<\mathrm{k}-\mathrm{r}$,
(ii) $\left(\mathrm{v},(\mathrm{p}+1) \bmod 2^{\mathrm{r}}\right)$, and
(iii) $\left(v,(p-1) \bmod 2^{r}\right)$.

The first link is called a cube edge, the remaining two, cycle edges. $\mathrm{CCC}_{\mathrm{k}}$ has $2^{\mathrm{k}}$ vertices and has degree 3.

The following is a recurrent interconnection pattern that is as powerful as the cube-connected cycles, at least in its ability to simulate composite algorithms. The cube-connected lines, $\mathrm{CCL}_{\mathrm{k}}$ (see Fig. 1) is simply a copy of $\mathrm{CCC}_{\mathrm{k}}$ with the edges from vertices $(\mathrm{v}, 0)$ to $\left(\mathrm{v}, 2^{\mathrm{r}}-1\right), 0 \leqslant \mathrm{v}<2^{\mathrm{k}-\mathrm{r}}$ deleted (we call the remaining cycle edges line edges, and the deleted cycle edges external edges). That is, the cycles of the cube-connected cycles are broken, and thus become lines. $\mathrm{CCL}_{\mathrm{k}}$ has $2^{\mathrm{k}}$ vertices and has degree 3 .

It is fairly easy to see that $\mathrm{CCL}_{\mathrm{k}}$ is recurrent. We need to differentiate the special case of $\mathrm{CCL}_{\mathrm{k}}$ when $k$ is of the form $2^{r}+r$, for some $r$. In this case we call $\mathrm{CCL}_{\mathrm{k}}$ a full cube-connected lines graph.
$\mathrm{CCL}_{1}$

$\mathrm{CCL}_{2}$

Fig. 1. The $2,4,8,16$, and 32 vertex cube-connected lines graphs, $\mathrm{CCL}_{1}$ through $\mathrm{CCL}_{5}$. Line-edges are drawn vertically; the remainder are cube-edges.

Fig. 2. $\mathrm{CCL}_{4}$ has one subgraph isomorphic to $\mathrm{CCL}_{3}$.

Lemma 3.1. If $\mathrm{k}=2^{\mathrm{r}}+\mathrm{r}$, then $\mathrm{CCL}_{\mathrm{k}+1}$ has exactly one subgraph isomorphic to $\mathrm{CCL}_{\mathrm{k}}$.

Proof. Suppose $\mathrm{k}=2^{\mathrm{r}}+\mathrm{r} . \mathrm{CCL}_{\mathrm{k}}$ has vertices ( $\mathrm{v}, \mathrm{p}$ ) with $0 \leqslant v<2^{k-r}, \quad 0 \leqslant p<2^{\mathrm{r}}$. Vertex ( $\mathrm{v}, \mathrm{p}$ ) is joined to the following vertices:
(i) $\left(\mathrm{v}^{(\mathrm{p}+1)}, \mathrm{p}\right), 0 \leqslant \mathrm{v}<2^{\mathrm{k}-\mathrm{r}}, 0 \leqslant \mathrm{p}<2^{\mathrm{r}}$,
(ii) $(\mathrm{v}, \mathrm{p}+1), 0 \leqslant \mathrm{v}<2^{\mathrm{k}-\mathrm{r}}, 0 \leqslant \mathrm{p}<2^{\mathrm{r}}-1$, and
(iii) $(\mathrm{v}, \mathrm{p}-1), 0 \leqslant \mathrm{v}<2^{\mathrm{k}-\mathrm{r}}, 0<\mathrm{p}<2^{\mathrm{r}}$.
$\mathrm{CCL}_{\mathrm{k}+1}$ has vertices ( $\mathrm{v}, \mathrm{p}$ ) with $0 \leqslant \mathrm{v}<2^{\mathrm{k}-\mathrm{r}}, 0 \leqslant$ $\mathrm{p}<2^{\mathrm{r}+1}$. Vertex ( $\mathrm{v}, \mathrm{p}$ ) is joined to the following vertices:
(i) $\left(\mathrm{v}^{(\mathrm{p}+1)}, \mathrm{p}\right), 0 \leqslant \mathrm{v}<2^{\mathrm{k}-\mathrm{r}}, 0 \leqslant \mathrm{p}<2^{\mathrm{r}}$,
(ii) $(\mathrm{v}, \mathrm{p}+1), 0 \leqslant \mathrm{v}<2^{\mathrm{k}-\mathrm{r}}, 0 \leqslant \mathrm{p}<2^{\mathrm{r}+1}-1$, and
(iii) $(\mathrm{v}, \mathrm{p}-1), 0 \leqslant \mathrm{v}<2^{\mathrm{k}-\mathrm{r}}, 0<\mathrm{p}<2^{\mathrm{r}+1}$.

Thus, $\mathrm{CCL}_{\mathrm{k}}$ looks exactly like $\mathrm{CCL}_{\mathrm{k}-1}$ with lines extended to double the length using vertices
without cube links (see Fig. 2). So, $\mathrm{CCL}_{\mathrm{k}+1}$ has exactly one subgraph isomorphic to $\mathrm{CCL}_{\mathbf{k}}$.

Lemma 3.2. If k is not of the form $2^{\mathrm{r}}+\mathrm{r}$, then $\mathrm{CCL}_{\mathrm{k}+1}$ has two disjoint subgraphs isomorphic to $\mathrm{CCL}_{\mathrm{k}}$.

Proof. Without loss of generality, suppose $\mathrm{k}<2^{\mathrm{r}}$ $+\mathrm{r} . \mathrm{CCL}_{\mathrm{k}}$ has vertices ( $\mathrm{v}, \mathrm{p}$ ) with $0 \leqslant \mathrm{v}<2^{\mathrm{k}-\mathrm{r}}$, $0 \leqslant \mathrm{p}<2^{\mathrm{r}}$. Vertex ( $\mathrm{v}, \mathrm{p}$ ) is joined to the following vertices:
(i) $\left(\mathrm{v}^{(\mathrm{p}+1)}, \mathrm{p}\right), 0 \leqslant \mathrm{v}<2^{\mathrm{k}-\mathrm{r}}, 0 \leqslant \mathrm{p}<\mathrm{k}-\mathrm{r}$,
(ii) $(\mathrm{v}, \mathrm{p}+1), 0 \leqslant \mathrm{v}<2^{\mathrm{k}-\mathrm{r}}, 0 \leqslant \mathrm{p}<2^{\mathrm{r}}-1$, and
(iii) $(\mathrm{v}, \mathrm{p}-1), 0 \leqslant \mathrm{v}<2^{\mathrm{k}-\mathrm{r}}, 0<\mathrm{p}<2^{\mathrm{r}}$.
$\mathrm{CCL}_{\mathrm{k}+1}$ has vertices $(\mathrm{v}, \mathrm{p})$ with $0 \leqslant \mathrm{v}<2^{\mathrm{k}-\mathrm{r}+1}$, $0 \leqslant \mathrm{p}<2^{\mathrm{r}}$. Vertex ( $\mathrm{v}, \mathrm{p}$ ) is joined to the following vertices:
(i) $\left(\mathrm{v}^{(\mathrm{p}+1)}, \mathrm{p}\right), \quad 0 \leqslant \mathrm{v}<2^{\mathrm{k}-\mathrm{r}+1}, \quad 0 \leqslant \mathrm{p}<\mathrm{k}-\mathrm{r}$ +1 ,
(ii) $(\mathrm{v}, \mathrm{p}+1), 0 \leqslant \mathrm{v}<2^{\mathrm{k}-\mathrm{r}+1}, 0 \leqslant \mathrm{p}<2^{\mathrm{r}}-1$. and
(iii) $(\mathrm{v}, \mathrm{p}-1), 0 \leqslant \mathrm{v}<2^{\mathrm{k}-\mathrm{r}+1}, 0<\mathrm{p}<2^{\mathrm{r}}$.

Thus, deleting the cube-edges from ( $v, p$ ) to ( $\mathrm{v}^{(\mathrm{p}+1)}, \mathrm{p}$ ) with $\mathrm{p}=\mathrm{k}-\mathrm{r}$ from $\mathrm{CCL}_{\mathrm{k}+1}$ gives two disjoint graphs isomorphic to $\mathrm{CCL}_{\mathrm{k}}$ (see Fig. 3).

Lemma 3.3. If $\mathrm{k}=2^{\mathrm{r}}+\mathrm{r}$ and $\mathrm{j}=2^{\mathrm{s}}+\mathrm{s}$, where $\mathrm{r} \geqslant \mathrm{s}$, then $\mathrm{CCL}_{\mathrm{k}}$ has exactly $2^{\mathrm{k}-\mathrm{j}}$ disjoint subgraphs isomorphic to $\mathrm{CCL}_{\mathrm{j}}$.

Fig. 3. $\mathrm{CCL}_{5}$ has two subgraphs isomorphic to $\mathrm{CCL}_{4}$.

Fig. 4. $\mathrm{CCL}_{3}$ has four subgraphs isomorphic to $\mathrm{CCL}_{1}$.

Proof. Suppose $\mathrm{k}=2^{\mathrm{r}}+\mathrm{r}$ and $\mathrm{j}=2^{\mathrm{s}}+\mathrm{s}$ for some $r \geqslant s \geqslant 0 . C_{j}$ has vertices (v, $p$ ), $0 \leqslant v<2^{2^{3}}, 0 \leqslant$ $\mathrm{p}<2^{\mathrm{s}}$. Vertex ( $\mathrm{v}, \mathrm{p}$ ) is joined to the following vertices:
(i) $\left(\mathrm{v}^{(\mathrm{p}+1)}, \mathrm{p}\right), \quad 0 \leqslant \mathrm{v}<2^{2^{s}}, 0 \leqslant \mathrm{p}<2^{\mathrm{s}}$,
(ii) $(\mathrm{v}, \mathrm{p}+1), 0 \leqslant \mathrm{v}<2^{2^{5}}, 0 \leqslant \mathrm{p}<2^{\mathrm{s}}-1$, and
(iii) $(\mathrm{v}, \mathrm{p}-1), 0 \leqslant \mathrm{v}<2^{2^{5}}, 0<\mathrm{p}<2^{\mathrm{s}}$.
$\mathrm{CCL}_{\mathrm{k}}$ has vertices ( $\left.\mathrm{v}, \mathrm{p}\right), 0 \leqslant \mathrm{v}<2^{2^{2}}, 0 \leqslant \mathrm{p}<2^{\mathrm{r}}$. Vertex ( $\mathrm{v}, \mathrm{p}$ ) is joined to the following vertices:
(i) $\left(\mathrm{v}^{(\mathrm{p}+1)}, \mathrm{p}\right), 0 \leqslant \mathrm{v}<2^{2^{r}}, 0 \leqslant \mathrm{p}<2^{\mathrm{r}}$,
(ii) $(\mathrm{v}, \mathrm{p}+1), 0 \leqslant \mathrm{v}<2^{2}, 0 \leqslant \mathrm{p}<2^{\mathrm{r}}-1$, and
(iii) $(\mathrm{v}, \mathrm{p}-1), 0 \leqslant \mathrm{v}<2^{2^{\mathrm{r}}}, 0<\mathrm{p}<2^{\mathrm{r}}$.

Deleting the line-edges between vertices ( v , i $2^{\mathrm{s}}-$ 1) and ( v , i $2^{\mathrm{s}}$ ) for $0 \leqslant \mathrm{v}<2^{2^{r}}, 0 \leqslant \mathrm{i}<2^{\mathrm{r}-\mathrm{s}}$, breaks $\mathrm{CCL}_{\mathrm{k}}$ into $2^{\mathrm{k}-\mathrm{j}}$ graphs isomorphic to $\mathrm{CCL}_{\mathrm{j}}$ (see Fig. 4). Thus, a full $\mathrm{CCL}_{\mathrm{k}}$ has $2^{\mathrm{k}-\mathrm{j}}$ disjoint subgraphs isomorphic to a full $\mathrm{CCL}_{\mathrm{j}}$.

Theorem 3.4. For $0 \leqslant \mathrm{j} \leqslant \mathrm{k}, \mathrm{CCL}_{\mathrm{k}}$ has at least $2^{\mathrm{k}-\mathrm{j}-1}$ disjoint subgraphs isomorphic to $\mathrm{CCL}_{\mathrm{j}}$.

Proof (Sketch). The result easily follows using the above lemmas. First, reduce $\mathrm{CCL}_{k}$ into subgraphs isomorphic to the next smaller full CCL, using Lemmas 3.1 and 3.2. If $\mathrm{CCL}_{\mathrm{j}}$ is encountered along the way, then this is sufficient. Next, using Lemma 3.3, reduce the full CCL immediately below $\mathrm{CCL}_{\mathrm{k}}$ into subgraphs isomorphic to the full CCL immediately above $\mathrm{CCL}_{\mathrm{j}}$. The latter can be reduced to CCL $_{\mathrm{J}}$ by application of Lemma 3.2.

In this entire process we only once have to reduce a nonfull CCL to subgraphs isomorphic to full ones. Thus, $\mathrm{CCL}_{\mathrm{k}}$ consists of $2^{\mathrm{k}-\mathrm{j}-1}$ subgraphs isomorphic to $\mathrm{CCL}_{\mathrm{j}}$.

Note that any attempt to increase the number of subgraphs from $2^{k-j-1}$ to $2^{k-j}$ is doomed to failure. For if $\mathrm{CCL}_{\mathrm{k}}$ had $2^{\mathrm{k}-\mathrm{j}}$ subgraphs isomorphic to $\mathrm{CCL}_{\mathrm{j}}$, it would then be recursive. Thus, by

Theorem 2.1 it would be much weaker than the cube-connected cycles for computing permutations. However, we have the following theorem.

Theorem 3.5. A cube-connected lines with $2^{\mathrm{k}}$ processors can simulate a $2^{\mathrm{k}}$ processor composite algorithm without asymptotic time loss.

Proof. The proof is almost identical to that for the cube-connected cycles [5]. In that proof:
(1) The pipelining phase utilizes a synchronous cyclic shift around the cycles. This can be replaced with a linear shift along the corresponding lines of the cube-connected lines graph, with wrap-around at the ends (at most doubling the time requirement).
(2) Communication within the cycles is performed using a procedure called Loopoper. A close examination of this procedure reveals that it never uses external edges, and thus can be executed on the cube-connected lines graph.

Thus, in particular, a parallel machine based on the cube-connected lines interconnection pattern can permute $n$ items in $O(\log n)$ time.

Reif and Valiant [6] have independently discovered a graph that is similar to the cubeconnected lines.
